# PROJECT DEVELOPMENT PHASE

1. Development Overview:

The development phase focuses on implementing Client Scripts and UI Policies in the ServiceNow Incident application. These configurations are used to improve the Incident form by controlling field behavior, validating user inputs, and dynamically changing the form based on user actions.

2. Client Script Development:

Client Scripts are developed to perform client-side actions when users interact with the Incident form. The required scripts are configured based on the project requirements.

❖ The Client Script can be used to:

- Validate Incident form inputs.
- Automatically populate or modify field values.
- Display messages when incorrect information is entered.
- Control field behavior based on user selections.
- Execute actions when the form is loaded, changed, or submitted.

- The scripts are tested on the Incident form to ensure that the expected behavior occurs without affecting other functionality.

3. UI Policy Development:

➢ UI Policies are configured to dynamically control the Incident form fields without requiring complex scripting. Based on the specified conditions, fields can be made mandatory, visible, or read-only.

➢ For example, a UI Policy can be created to make a particular Incident field mandatory when a specific condition is satisfied. UI Policy Actions are then configured for the required fields.

4. Development Testing:

After implementing the Client Scripts and UI Policies, the Incident form is tested with different conditions and field values. The configurations are checked to ensure that the fields behave according to the project requirements.

5. Expected Outcome:

The development phase results in a properly configured Incident form where Client Scripts and UI Policies work together to provide correct field validation, visibility, mandatory-field control, and improved user interaction.
